

# **Web Server: Racket HTTP Server**

Version 5.1

Jay McCarthy

February 14, 2011

This manual describes the internals of the Racket Web Server.

# 1 Dispatching Server

The Web Server is just a configuration of a dispatching server.

## 1.1 Dispatching Server Signatures

```
(require web-server/private/dispatch-server-sig)
```

The `web-server/private/dispatch-server-sig` library provides two signatures.

---

`dispatch-server^` : signature

The `dispatch-server^` signature is an alias for `web-server^`.

---

`(serve)`

```
→ (->* () (#:confirmation-channel (or/c false/c async-channel?)) (-> void))
```

Runs the server—the confirmation channel will be send an exception if one occurs starting the server or the port number if there is none—and returns a procedure that shuts down the server.

---

`(serve-ports ip op) → void`

`ip` : `input-port?`

`op` : `output-port?`

Serves a single connection represented by the ports `ip` and `op`.

---

`dispatch-server-config^` : signature

---

`port` : `tcp-listen-port?`

Specifies the port to serve on.

---

`listen-ip` : `(or/c string? false/c)`

Passed to `tcp-listen`.

---

`max-waiting` : `exact-integer?`

Passed to `tcp-listen`.

---

`initial-connection-timeout` : `integer?`

Specifies the initial timeout given to a connection.

---

```
(read-request c p port-addresses) → any/c boolean?  
c : connection?  
p : tcp-listen-port?  
port-addresses : (input-port? . -> . (values string? string?))
```

Defines the way the server reads requests off connections to be passed to `dispatch`.

---

```
dispatch : (-> connection? any/c void)
```

How to handle requests.

## 1.2 Dispatching Server Unit

```
(require web-server/private/dispatch-server-unit)
```

The `web-server/private/dispatch-server-unit` module provides the unit that actually implements a dispatching server.

---

```
dispatch-server@ : (unit/c (import tcp^ dispatch-server-config^)  
                        (export dispatch-server^))
```

Runs the dispatching server config in a very basic way, except that it uses §5.2 “Connection Manager” to manage connections.

## 1.3 Threads and Custodians

The dispatching server runs in a dedicated thread. Every time a connection is initiated, a new thread is started to handle it. Connection threads are created inside a dedicated custodian that is a child of the server’s custodian. When the server is used to provide servlets, each servlet also receives a new custodian that is a child of the server’s custodian **not** the connection custodian.

## 2 Dispatchers

Since the Web Server is really just a particular configuration of a dispatching server, there are several dispatchers that are defined to support the Web Server. Other dispatching servers may find these useful. In particular, if you want a peculiar processing pipeline for your Web Server installation, refer to this documentation.

### 2.1 General

```
(require web-server/dispatchers/dispatch)
```

This module provides a few functions for dispatchers in general.

---

```
dispatcher/c : contract?
```

Equivalent to `(-> connection? request? void)`.

---

```
(dispatcher-interface-version/c any) → boolean?  
any : any/c
```

Equivalent to `(symbols 'v1)`

---

```
(struct exn:dispatcher ()  
      #:extra-constructor-name make-exn:dispatcher)
```

An exception thrown to indicate that a dispatcher does not apply to a particular request.

---

```
(next-dispatcher) → void
```

Raises a `exn:dispatcher`

As the `dispatcher/c` contract suggests, a dispatcher is a function that takes a connection and request object and does something to them. Mostly likely it will generate some response and output it on the connection, but it may do something different. For example, it may apply some test to the request object, perhaps checking for a valid source IP address, and error if the test is not passed, and call `next-dispatcher` otherwise.

Consider the following example dispatcher, that captures the essence of URL rewriting:

```
; (url? -> url?) dispatcher/c -> dispatcher/c  
(lambda (rule inner)  
  (lambda (conn req)
```

```

; Call the inner dispatcher...
(inner conn
  ; with a new request object...
  (struct-copy request req
    ; with a new URL!
    [request-uri (rule (request-uri req))]))))

```

## 2.2 Mapping URLs to Paths

```
(require web-server/dispatchers/filesystem-map)
```

This module provides a means of mapping URLs to paths on the filesystem.

---

```
url->path/c : contract?
```

This contract is equivalent to `(->* (url?) (path? (listof path-element?)))`. The returned `path?` is the path on disk. The list is the list of path elements that correspond to the path of the URL.

---

```
(make-url->path base) → url->path/c
  base : path-string?
```

The `url->path/c` returned by this procedure considers the root URL to be `base`. It ensures that `".."`s in the URL do not escape the `base` and removes them silently otherwise.

---

```
(make-url->valid-path url->path) → url->path/c
  url->path : url->path/c
```

Runs the underlying `url->path`, but only returns if the path refers to a file that actually exists. If it does not, then the suffix elements of the URL are removed until a file is found. If this never occurs, then an error is thrown.

This is primarily useful for dispatchers that allow path information after the name of a service to be used for data, but where the service is represented by a file. The most prominent example is obviously servlets.

---

```
(filter-url->path regex url->path) → url->path/c
  regex : regexp?
  url->path : url->path/c
```

Runs the underlying `url->path` but will only return if the path, when considered as a string, matches the `regex`. This is useful to disallow strange files, like GIFs,

from being considered servlets when using the servlet dispatchers. It will return a `exn:fail:filesystem:exists?` exception if the path does not match.

## 2.3 Sequencing

```
(require web-server/dispatchers/dispatch-sequencer)
```

The `web-server/dispatchers/dispatch-sequencer` module defines a dispatcher constructor that invokes a sequence of dispatchers until one applies.

---

```
(make dispatcher ...) → dispatcher/c  
  dispatcher : dispatcher/c
```

Invokes each `dispatcher`, invoking the next if the first calls `next-dispatcher`. If no `dispatcher` applies, then it calls `next-dispatcher` itself.

## 2.4 Timeouts

```
(require web-server/dispatchers/dispatch-timeout)
```

The `web-server/dispatchers/dispatch-timeout` module defines a dispatcher constructor that changes the timeout on the connection and calls the next dispatcher.

---

```
(make new-timeout) → dispatcher/c  
  new-timeout : integer?
```

Changes the timeout on the connection with `adjust-connection-timeout!` called with `new-timeout`.

## 2.5 Lifting Procedures

```
(require web-server/dispatchers/dispatch-lift)
```

The `web-server/dispatchers/dispatch-lift` module defines a dispatcher constructor.

---

```
(make proc) → dispatcher/c  
  proc : (request? . -> . response?)
```

Constructs a dispatcher that calls *proc* on the request object, and outputs the response to the connection.

## 2.6 Filtering Requests

```
(require web-server/dispatchers/dispatch-filter)
```

The `web-server/dispatchers/dispatch-filter` module defines a dispatcher constructor that calls an underlying dispatcher with all requests that pass a predicate.

---

```
(make regex inner) → dispatcher/c  
  regex : regexp?  
  inner : dispatcher/c
```

Calls *inner* if the URL path of the request, converted to a string, matches *regex*. Otherwise, calls *next-dispatcher*.

## 2.7 Procedure Invocation upon Request

```
(require web-server/dispatchers/dispatch-pathprocedure)
```

The `web-server/dispatchers/dispatch-pathprocedure` module defines a dispatcher constructor for invoking a particular procedure when a request is given to a particular URL path.

---

```
(make path proc) → dispatcher/c  
  path : string?  
  proc : (request? . -> . response?)
```

Checks if the request URL path as a string is equal to *path* and if so, calls *proc* for a response.

This is used in the standard Web Server pipeline to provide a URL that refreshes the password file, servlet cache, etc.

## 2.8 Logging

```
(require web-server/dispatchers/dispatch-log)
```

The `web-server/dispatchers/dispatch-log` module defines a dispatcher constructor for transparent logging of requests.

---

`format-req/c` : `contract?`

Equivalent to `(-> request? string?)`.

---

`paren-format` : `format-req/c`

Formats a request by:

```
(format
  "~s\n"
  (list 'from (request-client-ip req)
        'to (request-host-ip req)
        'for (url->string (request-uri req)) 'at
        (date->string
          (seconds->date (current-seconds)) #t)))
```

---

`extended-format` : `format-req/c`

Formats a request by:

```
(format
  "~s\n"
  '((client-ip ,(request-client-ip req))
    (host-ip ,(request-host-ip req))
    (referer
     ,(let ([R (headers-assq*
                #"Referer"
                (request-headers/raw req))])
        (if R
            (header-value R)
            #f)))
    (uri ,(url->string (request-uri req)))
    (time ,(current-seconds))))
```

---

`apache-default-format` : `format-req/c`

Formats a request like Apache's default.

---

`log-format/c` : `contract?`

Equivalent to `(symbols 'parenthesized-default 'extended 'apache-default)`.

---

```
(log-format->format id) → format-req/c
  id : log-format/c
```

Maps `'parenthesized-default` to `paren-format`, `'extended` to `extended-format`, and `'apache-default` to `apache-default-format`.

---

```
(make [#:format format #:log-path log-path]) → dispatcher/c
  format : format-req/c = paren-format
  log-path : path-string? = "log"
```

Logs requests to `log-path` by using `format` to format the requests. Then invokes `next-dispatcher`.

## 2.9 Password Protection

```
(require web-server/dispatchers/dispatch-passwords)
```

The `web-server/dispatchers/dispatch-passwords` module defines a dispatcher constructor that performs HTTP Basic authentication filtering.

---

```
denied?/c : contract?
```

Equivalent to `(-> request? (or/c false/c string?))`. The return is the authentication realm as a string if the request is not authorized and `#f` if the request *is* authorized.

---

```
(make denied?
  [#:authentication-responder authentication-responder])
→ dispatcher/c
  denied? : denied?/c
  authentication-responder : (url? header? . -> . response?)
                           = (gen-authentication-responder "forbidden.html")
```

A dispatcher that checks if the request is denied based on `denied?`. If so, then `authentication-responder` is called with a `header` that requests credentials. If not, then `next-dispatcher` is invoked.

---

```
authorized?/c : contract?
```

Equivalent to `(-> string? (or/c false/c bytes?) (or/c false/c bytes?) (or/c false/c string?))`. The input is the URI as a string and the username and passwords as bytes. The return is the authentication realm as a string if the user is not authorized and `#f` if the request is authorized.

---

```
(make-basic-denied?/path password-file)
→ (-> void) authorized?/c
password-file : path-string?
```

Creates an authorization procedure based on the given password file. The first returned value is a procedure that refreshes the password cache used by the authorization procedure.

`password-file` is parsed as:

```
(list ([domain : string?]
      [path : string?] ; This string is interpreted as a regex
      (list [user : symbol?]
            [pass : string?])
      ...))
...)
```

For example:

```
'(("secret stuff" "/secret(/.*)?" (bubba "bbq") (Billy "BoB")))
```

## 2.10 Virtual Hosts

```
(require web-server/dispatchers/dispatch-host)
```

The `web-server/dispatchers/dispatch-host` module defines a dispatcher constructor that calls a different dispatcher based upon the host requested.

---

```
(make lookup-dispatcher) → dispatcher/c
lookup-dispatcher : (symbol? . -> . dispatcher/c)
```

Extracts a host from the URL requested, or the Host HTTP header, calls `lookup-dispatcher` with the host, and invokes the returned dispatcher. If no host can be extracted, then `'none` is used.

## 2.11 Serving Files

```
(require web-server/dispatchers/dispatch-files)
```

The `web-server/dispatchers/dispatch-files` module allows files to be served. It defines a dispatcher construction procedure.

---

```
(make #:url->path url->path
      [#:path->mime-type path->mime-type
       #:indices indices]) → dispatcher/c
url->path : url->path/c
path->mime-type : (path? . -> . bytes?)
                 = (lambda (path) TEXT/HTML-MIME-TYPE)
indices : (listof string?) = (list "index.html" "index.htm")
```

Uses `url->path` to extract a path from the URL in the request object. If this path does not exist, then the dispatcher does not apply and `next-dispatcher` is invoked. If the path is a directory, then the `indices` are checked in order for an index file to serve. In that case, or in the case of a path that is a file already, `path->mime-type` is consulted for the MIME Type of the path. The file is then streamed out the connection object.

This dispatcher supports HTTP Range GET requests and HEAD requests.

## 2.12 Serving Servlets

```
(require web-server/dispatchers/dispatch-servlets)
```

The `web-server/dispatchers/dispatch-servlets` module defines a dispatcher constructor that runs servlets.

---

```
url->servlet/c : contract?
```

Equivalent to `(-> url? servlet?)`

---

```
(make-cached-url->servlet url->path
                          path->servlet)
→ (-> void) url->servlet/c
url->path : url->path/c
path->servlet : path->servlet/c
```

The first return value flushes the cache. The second is a procedure that uses `url->path` to resolve the URL to a path, then uses `path->servlet` to resolve that path to a servlet, caching the results in an internal table.

---

```
(make url->servlet
      [#:responders-servlet-loading responders-servlet-loading
       #:responders-servlet responders-servlet])
→ dispatcher/c
url->servlet : url->servlet/c
responders-servlet-loading : (url? exn? . -> . can-be-response?)
                           = servlet-loading-responder
responders-servlet : (url? exn? . -> . can-be-response?)
                    = servlet-error-responder
```

This dispatcher runs racket servlets, using *url->servlet* to resolve URLs to the underlying servlets. If servlets have errors loading, then *responders-servlet-loading* is used. Other errors are handled with *responders-servlet*. If a servlet raises calls *next-dispatcher*, then the signal is propagated by this dispatcher.

### 2.12.1 Setting Up Servlets

```
(require web-server/servlet/setup)
```

This module is used internally to build and load servlets. It may be useful to those who are trying to extend the server.

---

```
(make-v1.servlet directory timeout start) → servlet?
directory : path-string?
timeout : integer?
start : (request? . -> . can-be-response?)
```

Creates a version 1 servlet that uses *directory* as its current directory, a timeout manager with a *timeout* timeout, and *start* as the request handler.

---

```
(make-v2.servlet directory manager start) → servlet?
directory : path-string?
manager : manager?
start : (request? . -> . can-be-response?)
```

Creates a version 2 servlet that uses *directory* as its current directory, a *manager* as the continuation manager, and *start* as the request handler.

---

```
(make-stateless.servlet directory
                          stuffer
                          manager
                          start) → servlet?
```

```
directory : path-string?
stuffer   : (stuffer/c serializable? bytes?)
manager   : manager?
start     : (request? . -> . can-be-response?)
```

Creates a stateless `web-server` servlet that uses `directory` as its current directory, `stuffer` as its stuffer, and `manager` as the continuation manager, and `start` as the request handler.

---

```
default-module-specs : (listof module-path?)
```

The modules that the Web Server needs to share with all servlets.

---

```
path->servlet/c : contract?
```

Equivalent to `(-> path? servlet?)`.

---

```
(make-default-path->servlet
 [#:make-servlet-namespace make-servlet-namespace
  #:timeouts-default-servlet timeouts-default-servlet])
-> path->servlet/c
 make-servlet-namespace : make-servlet-namespace/c
                        = (make-make-servlet-namespace)
 timeouts-default-servlet : integer? = 30
```

Constructs a procedure that loads a servlet from the path in a namespace created with `make-servlet-namespace`, using a timeout manager with `timeouts-default-servlet` as the default timeout (if no manager is given.)

### 2.12.2 Servlet Namespaces

```
(require web-server/configuration/namespace)
```

This module provides a function to help create the `make-servlet-namespace` procedure needed by the `make` function of `web-server/dispatchers/dispatch-servlets`.

---

```
make-servlet-namespace/c : contract?
```

Equivalent to

```
(->* ()
 (#:additional-specs (listof module-path?))
 namespace?)
```

---

```
(make-make-servlet-namespace #:to-be-copied-module-specs to-be-copied-module-specs)
→ make-servlet-namespace/c
   to-be-copied-module-specs : (listof module-path?)
```

This function creates a function that when called will construct a new `namespace` that has all the modules from `to-be-copied-module-specs` and `additional-specs`, as well as `racket` and `mred`, provided they are already attached to the `(current-namespace)` of the call-site.

Example:

```
(make-make-servlet-namespace
 #:to-be-copied-module-specs '((lib "database.rkt" "my-module")))
```

### Why this is useful

A different namespace is needed for each servlet, so that if servlet A and servlet B both use a stateful module C, they will be isolated from one another. We see the Web Server as an operating system for servlets, so we inherit the isolation requirement on operating systems.

However, there are some modules which must be shared. If they were not, then structures cannot be passed from the Web Server to the servlets, because Racket's structures are generative.

Since, on occasion, a user will actually want servlets A and B to interact through module C. A custom `make-servlet-namespace` can be created, through this procedure, that attaches module C to all servlet namespaces. Through other means (see §2 “Dispatchers”) different sets of servlets can share different sets of modules.

### 2.12.3 Internal Servlet Representation

```
(require web-server/private/servlet)
```

---

```
(struct servlet (custodian namespace manager directory handler)
 #:constructor-name make-servlet
 #:mutable)
custodian : custodian?
namespace : namespace?
manager   : manager?
directory : path-string?
handler   : (request? . -> . can-be-response?)
```

Instances of this structure hold the necessary parts of a servlet: the `custodian` responsible for the servlet's resources, the `namespace` the servlet is executed within, the `manager` responsible for the servlet's continuations, the current `directory` of the servlet, and the `handler` for all requests to the servlet.

## 2.13 Statistics

```
(require web-server/dispatchers/dispatch-stat)
```

The `web-server/dispatchers/dispatch-stat` module provides services related to performance statistics.

---

```
(make-gc-thread time) → thread?  
time : integer?
```

Starts a thread that calls `(collect-garbage)` every `time` seconds.

---

```
(make) → dispatcher/c
```

Returns a dispatcher that prints memory usage on every request.

## 2.14 Limiting Requests

```
(require web-server/dispatchers/limit)
```

The `web-server/dispatchers/limit` module provides a wrapper dispatcher that limits how many requests are serviced at once.

---

```
(make limit inner [#:over-limit over-limit]) → dispatcher/c  
limit : number?  
inner : dispatcher/c  
over-limit : (symbols 'block 'kill-new 'kill-old) = 'block
```

Returns a dispatcher that defers to `inner` for work, but will forward a maximum of `limit` requests concurrently.

If there are no additional spaces inside the limit and a new request is received, the `over-limit` option determines what is done. The default `'block` causes the new request to block until an old request is finished being handled. If `over-limit` is `'kill-new`, then the new request handler is killed—a form of load-shedding. If `over-limit` is `'kill-old`, then the oldest request handler is killed—prioritizing new connections over old. (This setting is a

little dangerous because requests might never finish if there is constant load.)

Consider this example:

```
#lang racket

(require web-server/web-server
         web-server/http
         web-server/http/response
         (prefix-in limit: web-server/dispatchers/limit)
         (prefix-in filter: web-server/dispatchers/dispatch-filter)
         (prefix-in sequencer: web-server/dispatchers/dispatch-
sequencer))

(serve #:dispatch
      (sequencer:make
       (filter:make
        #rx"/limited"
        (limit:make
         5
         (lambda (conn req)
           (output-response/method
            conn
            (response/full
             200 #"Okay"
             (current-seconds) TEXT/HTML-MIME-TYPE
             empty
             (list (string->bytes/utf-8
                   (format "hello world ~a"
                           (sort (build-list 100000 (lambda x (random 100)))
                                   <))))))
            (request-method req)))
        #:over-limit 'block))
      (lambda (conn req)
        (output-response/method
         conn
         (response/full 200 #"Okay"
                        (current-seconds) TEXT/HTML-MIME-TYPE
                        empty
                        (list #"<html><body>Unlimited</body></html>"))
         (request-method req)))
      #:port 8080)

(do-not-return)
```

### 3 Launching Servers

```
(require web-server/web-server)
```

This module provides functions for launching dispatching servers.

---

```
(serve
 #:dispatch dispatch
 [#:confirmation-channel confirmation-channel
 #:connection-close? connection-close?
 #:tcp@ tcp@
 #:port port
 #:listen-ip listen-ip
 #:max-waiting max-waiting
 #:initial-connection-timeout initial-connection-timeout])
→ (-> void)
dispatch : dispatcher/c
confirmation-channel : (or/c false/c async-channel?) = #f
connection-close? : boolean? = #f
tcp@ : (unit/c (import) (export tcp^)) = raw:tcp@
port : tcp-listen-port? = 80
listen-ip : (or/c string? false/c) = #f
max-waiting : integer? = 40
initial-connection-timeout : integer? = 60
```

Constructs an appropriate `dispatch-server-config^`, invokes the `dispatch-server@`, and calls its `serve` function.

If `connection-close?` is `#t`, then every connection is closed after one request. Otherwise, the client decides based on what HTTP version it uses.

The `#:tcp@` keyword is provided for building an SSL server. See §6.3 “How do I set up the server to use HTTPS?”.

Here’s an example of a simple web server that serves files from a given path:

```
(define (start-file-server base)
 (serve
 #:dispatch
 (files:make
 #:url->path (make-url->path base)
 #:path->mime-type
 (lambda (path)
  #"application/octet-stream"))
 #:port 8080))
```

---

```

(serve/ports
 #:dispatch dispatch
 [#:confirmation-channel confirmation-channel
 #:connection-close? connection-close?
 #:tcp@ tcp@
 #:ports ports
 #:listen-ip listen-ip
 #:max-waiting max-waiting
 #:initial-connection-timeout initial-connection-timeout])
→ (-> void)
dispatch : dispatcher/c
confirmation-channel : (or/c false/c async-channel?) = #f
connection-close? : boolean? = #f
tcp@ : (unit/c (import) (export tcp^)) = raw:tcp@
ports : (listof tcp-listen-port?) = (list 80)
listen-ip : (or/c string? false/c) = #f
max-waiting : integer? = 40
initial-connection-timeout : integer? = 60

```

Calls `serve` multiple times, once for each port, and returns a function that shuts down all of the server instances.

---

```

(serve/ips+ports
 #:dispatch dispatch
 [#:confirmation-channel confirmation-channel
 #:connection-close? connection-close?
 #:tcp@ tcp@
 #:ips+ports ips+ports
 #:max-waiting max-waiting
 #:initial-connection-timeout initial-connection-timeout])
→ (-> void)
dispatch : dispatcher/c
confirmation-channel : (or/c false/c async-channel?) = #f
connection-close? : boolean? = #f
tcp@ : (unit/c (import) (export tcp^)) = raw:tcp@
ips+ports : (listof (cons/c (or/c string? false/c) (listof tcp-listen-port?)))
           = (list (cons #f (list 80)))
max-waiting : integer? = 40
initial-connection-timeout : integer? = 60

```

Calls `serve/ports` multiple times, once for each `ip`, and returns a function that shuts down all of the server instances.

---

```

(serve/web-config@ config@ [#:tcp@ tcp@]) → (-> void)

```

```

config@ : (unit/c (import) (export web-config^))
tcp@ : (unit/c (import) (export tcp^)) = raw:tcp@

```

Starts the Web Server with the settings defined by the given `web-config^` unit.

It is very useful to combine this with `configuration-table->web-config@` and `configuration-table-sexpr->web-config@`:

```

(serve/web-config@
 (configuration-table->web-config@
  default-configuration-table-path))

```

---

```

(do-not-return) → void

```

This function does not return. If you are writing a script to load the Web Server you are likely to want to call this functions at the end of your script.

### 3.1 Simple Single Servlet Servers

```

(require web-server/servlet-dispatch)

```

These functions optimize the construction of dispatchers and launching of servers for single servlets and interactive development.

---

```

(dispatch/servlet
 start
 [#:regexp regexp
 #:stateless? stateless?
 #:stuffer stuffer
 #:manager manager
 #:current-directory servlet-current-directory])
→ dispatcher/c
 start : (request? . -> . response?)
 regexp : regexp? = #rx""
 stateless? : boolean? = #f
 stuffer : (stuffer/c serializable? bytes?) = default-stuffer
 manager : manager?
         = (make-threshold-LRU-manager #f (* 1024 1024 64))
 servlet-current-directory : path-string? = (current-directory)

```

`serve/servlet` starts a server and uses a particular dispatching sequence. For some applications, this nails down too much, but users are conflicted, because the interface is so convenient. For those users, `dispatch/servlet` does the hardest part of `serve/servlet` and constructs a dispatcher just for the `start` servlet.

The dispatcher responds to requests that match *regexp*. The current directory of servlet execution is *servlet-current-directory*.

If *stateless?* is true, then the servlet is run as a stateless

```
#lang web-server
```

module and *stuffer* is used as the stuffer.

The servlet is loaded with *manager* as its continuation manager. (The default manager limits the amount of memory to 64 MB and deals with memory pressure as discussed in the [make-threshold-LRU-manager](#) documentation.)

The servlet is run in the (*current-namespace*).

---

```
(serve/launch/wait make-dispatcher
  [#:connection-close? connection-close?
   #:launch-path launch-path
   #:banner? banner?
   #:listen-ip listen-ip
   #:port port
   #:ssl-cert ssl-cert
   #:ssl-key ssl-key])
→ void
make-dispatcher : (semaphore? . -> . dispatcher/c)
connection-close? : boolean? = #f
launch-path : (or/c false/c string?) = #f
banner? : boolean? = #f
listen-ip : (or/c false/c string?) = "127.0.0.1"
port : number? = 8000
ssl-cert : (or/c false/c path-string?) = #f
ssl-key : (or/c false/c path-string?) = #f
```

The other interesting part of *serve/servlet* is its ability to start up a server and immediately launch a browser at it. This is provided by *serve/launch/wait*.

It starts a server using the result of *make-dispatcher* as the dispatcher. *make-dispatcher* is supplied a semaphore that if posted, will cause the server to quit.

If *launch-path* is not false, then a browser is launched with that path appended to the URL to the server itself.

If *banner?* is true, then a banner is printed informing the user of the server's URL.

The server listens on *listen-ip* and port *port*. If *listen-ip* is *#f*, then the server accepts connections to all of the listening machine's addresses. Otherwise, the server accepts

connections only at the interface(s) associated with the given string. For example, providing "127.0.0.1" (the default) as *listen-ip* creates a server that accepts only connections to "127.0.0.1" (the loopback interface) from the local machine.

If *ssl-key* and *ssl-cert* are not false, then the server runs in HTTPS mode with *ssl-cert* and *ssl-key* as paths to the certificate and private key.

If *connection-close?* is #t, then every connection is closed after one request. Otherwise, the client decides based on what HTTP version it uses.

## 4 Web Servers

A Web server is a unit with the `web-server^` signature. The most common way to construct one is to provide a `web-config^` unit to the `web-server@` unit. The most common way to construct a `web-config^` unit is to use `configuration-table->web-config@` to produce one from a configuration table file, such as the one that is shipped with Racket in `default-configuration-table-path`.

### 4.1 Server Units

#### 4.1.1 Signature

```
(require web-server/web-server-sig)
```

---

`web-server^` : signature

---

```
(serve) → (-> void)
```

Runs the server and returns a procedure that shuts down the server.

---

```
(serve-ports ip op) → void  
ip : input-port?  
op : output-port?
```

Serves a single connection represented by the ports `ip` and `op`.

#### 4.1.2 Unit

```
(require web-server/web-server-unit)
```

---

```
web-server@ : (unit/c (web-config^ tcp^)  
                  (web-server^))
```

Uses the `web-config^` to construct a `dispatcher/c` function that sets up one virtual host dispatcher, for each virtual host in the `web-config^`, that sequences the following operations:

- Logs the incoming request with the given format to the given file
- Performs HTTP Basic Authentication with the given password file

- Allows the `"/conf/refresh-passwords"` URL to refresh the password file.
- Allows the `"/conf/collect-garbage"` URL to call the garbage collector.
- Allows the `"/conf/refresh-servlets"` URL to refresh the servlets cache.
- Execute servlets in the mapping URLs to the given servlet root directory under htdocs.
- Serves files under the `"/"` URL in the given htdocs directory.

Using this `dispatcher/c`, it loads a dispatching server that provides `serve` and `serve-ports` functions that operate as expected.

## 4.2 Configuration Units

### 4.2.1 Signature

```
(require web-server/web-config-sig)
```

---

```
web-config^ : signature
```

Provides contains the following identifiers.

---

```
max-waiting : integer?
```

Passed to `tcp-accept`.

---

```
virtual-hosts : (string? . -> . host?)
```

Contains the configuration of individual virtual hosts.

---

```
initial-connection-timeout : integer?
```

Specifies the initial timeout given to a connection.

---

```
port : port-number?
```

Specifies the port to serve HTTP on.

---

```
listen-ip : (or/c false/c string?)
```

Passed to `tcp-listen`.

---

```
make-servlet-namespace : make-servlet-namespace/c
```

Passed to `servlets:make` through `make-default-path->servlet`.

## 4.2.2 Unit

```
(require web-server/web-config-unit)
```

---

```
(configuration-table->web-config@
  path
  [#:port port
   #:listen-ip listen-ip
   #:make-servlet-namespace make-servlet-namespace])
→ (unit/c (import) (export web-config^))
  path : path-string?
  port : (or/c false/c port-number?) = #f
  listen-ip : (or/c false/c string?) = #f
  make-servlet-namespace : make-servlet-namespace/c
                        = (make-make-servlet-namespace)
```

Reads the S-expression at *path* and calls `configuration-table-sexpr->web-config@` appropriately.

---

```
(configuration-table-sexpr->web-config@
  sexpr
  [#:web-server-root web-server-root
   #:port port
   #:listen-ip listen-ip
   #:make-servlet-namespace make-servlet-namespace])
→ (unit/c (import) (export web-config^))
  sexpr : list?
  web-server-root : path-string?
                  = (directory-part default-configuration-table-path)
  port : (or/c false/c port-number?) = #f
  listen-ip : (or/c false/c string?) = #f
  make-servlet-namespace : make-servlet-namespace/c
                        = (make-make-servlet-namespace)
```

Parses *sexpr* as a configuration-table and constructs a `web-config^` unit.

## 4.3 Configuration Table

```
(require web-server/configuration/configuration-table)
```

This module provides functions for reading, writing, parsing, and printing `configuration-table` structures.

---

`default-configuration-table-path` : `path?`

The default configuration table S-expression file.

---

`configuration-table-sexpr?` : `(any . -> . boolean?)`

Equivalent to `list?`.

---

`(sexpr->configuration-table sexpr)` → `configuration-table?`  
`sexpr` : `configuration-table-sexpr?`

This function converts a `configuration-table` from an S-expression.

---

`(configuration-table->sexpr ctable)`  
→ `configuration-table-sexpr?`  
`ctable` : `configuration-table?`

This function converts a `configuration-table` to an S-expression.

```
'((port ,integer?)
  (max-waiting ,exact-integer?)
  (initial-connection-timeout ,integer?)
  (default-host-table
   ,host-table-sexpr?)
  (virtual-host-table
   (list ,symbol? ,host-table-sexpr?)
   ...))
```

where a `host-table-sexpr` is:

```
'(host-table
  (default-indices ,string? ...)
  (log-format ,symbol?)
  (messages
   (servlet-message ,path-string?)
   (authentication-message ,path-string?)
   (servlets-refreshed ,path-string?)
   (passwords-refreshed ,path-string?)
   (file-not-found-message ,path-string?)
   (protocol-message ,path-string?)
   (collect-garbage ,path-string?))
  (timeouts
   (default-servlet-timeout ,integer?)
   (password-connection-timeout ,integer?))
```

```

(servlet-connection-timeout ,integer?)
(file-per-byte-connection-timeout ,integer?)
(file-base-connection-timeout ,integer))
(paths
 (configuration-root ,path-string?)
 (host-root ,path-string?)
 (log-file-path ,path-string?)
 (file-root ,path-string?)
 (servlet-root ,path-string?)
 (mime-types ,path-string?)
 (password-authentication ,path-string?)))

```

In this syntax, the `'messages` paths are relative to the `'configuration-root` directory. All the paths in `'paths` except for `'servlet-root` are relative to `'host-root` (other than `'host-root` obviously.) The `'servlet-root` path is relative to `'file-root`.

Allowable `'log-formats` are those accepted by `log-format->format`.

Note: You almost always want to leave everything in the `'paths` section the default except the `'host-root`.

---

```

(read-configuration-table path) → configuration-table?
  path : path-string?

```

This function reads a `configuration-table` from `path`.

---

```

(write-configuration-table ctable path) → void
  ctable : configuration-table?
  path : path-string?

```

This function writes a `configuration-table` to `path`.

## 4.4 Configuration Table Structure

```

(require web-server/configuration/configuration-table-structs)

```

This module provides the following structures that represent a standard configuration (see §4.1 “Server Units”) of the Web Server . The contracts on this structure influence the valid types of values in the configuration table S-expression file format described in §4.3 “Configuration Table”.

---

```
(struct configuration-table (port
                            max-waiting
                            initial-connection-timeout
                            default-host
                            virtual-hosts)
  #:extra-constructor-name make-configuration-table)
port : port-number?
max-waiting : natural-number/c
initial-connection-timeout : natural-number/c
default-host : host-table?
virtual-hosts : (listof (cons/c string? host-table?))
```

---

```
(struct host-table (indices log-format messages timeouts paths)
  #:extra-constructor-name make-host-table)
indices : (listof string?)
log-format : symbol?
messages : messages?
timeouts : timeouts?
paths : paths?
```

---

```
(struct host (indices
             log-format
             log-path
             passwords
             responders
             timeouts
             paths)
  #:extra-constructor-name make-host)
indices : (listof string?)
log-format : symbol?
log-path : (or/c false/c path-string?)
passwords : (or/c false/c path-string?)
responders : responders?
timeouts : timeouts?
paths : paths?
```

---

```
(struct responders (servlet
                  servlet-loading
                  authentication
                  servlets-refreshed
                  passwords-refreshed
                  file-not-found
                  protocol
                  collect-garbage)
                  #:extra-constructor-name make-responders)
servlet : (url? any/c . -> . response?)
servlet-loading : (url? any/c . -> . response?)
authentication : (url? (cons/c symbol? string?) . -> . response?)
servlets-refreshed : (-> response?)
passwords-refreshed : (-> response?)
file-not-found : (request? . -> . response?)
protocol : (url? . -> . response?)
collect-garbage : (-> response?)
```

---

```
(struct messages (servlet
                 authentication
                 servlets-refreshed
                 passwords-refreshed
                 file-not-found
                 protocol
                 collect-garbage)
                 #:extra-constructor-name make-messages)
servlet : string?
authentication : string?
servlets-refreshed : string?
passwords-refreshed : string?
file-not-found : string?
protocol : string?
collect-garbage : string?
```

---

```
(struct timeouts (default-servlet
                 password
                 servlet-connection
                 file-per-byte
                 file-base)
                 #:extra-constructor-name make-timeouts)
default-servlet : number?
password : number?
servlet-connection : number?
```

```
file-per-byte : number?
file-base : number?
```

---

```
(struct paths (conf
  host-base
  log
  htdocs
  servlet
  mime-types
  passwords)
  #:extra-constructor-name make-paths)
conf : (or/c false/c path-string?)
host-base : (or/c false/c path-string?)
log : (or/c false/c path-string?)
htdocs : (or/c false/c path-string?)
servlet : (or/c false/c path-string?)
mime-types : (or/c false/c path-string?)
passwords : (or/c false/c path-string?)
```

## 4.5 Standard Responders

```
(require web-server/configuration/responders)
```

This module provides some functions that help constructing HTTP responders. These functions are used by the default dispatcher constructor (see §4.1 “Server Units”) to turn the paths given in the `configuration-table` into responders for the associated circumstance.

---

```
(file-response http-code
  short-version
  text-file
  header ...) → response?
http-code : natural-number/c
short-version : string?
text-file : string?
header : header?
```

Generates a `response?` with the given `http-code` and `short-version` as the corresponding fields; with the content of the `text-file` as the body; and, with the `headers` as, you guessed it, headers.

This does not cause redirects to a well-known URL, such as “`conf/not-found.html`”, but rather use the contents of “`not-found.html`” (for example) as its contents. Therefore, any relative URLs in `text-file` are relative to whatever URL `file-response` is used to

respond *to*. Thus, you should probably use absolute URLs in these files.

---

```
(servlet-loading-responder url exn) → response?  
  url : url?  
  exn : exn?
```

Gives *exn* to the `current-error-handler` and response with a stack trace and a "Servlet didn't load" message.

---

```
(gen-servlet-not-found file) → ((url url?) . -> . response?)  
  file : path-string?
```

Returns a function that generates a standard "Servlet not found." error with content from *file*.

---

```
(servlet-error-responder url exn) → response?  
  url : url?  
  exn : exn?
```

Gives *exn* to the `current-error-handler` and response with a stack trace and a "Servlet error" message.

---

```
(gen-servlet-responder file)  
→ ((url url?) (exn any/c) . -> . response?)  
  file : path-string?
```

Prints the *exn* to standard output and responds with a "Servlet error." message with content from *file*.

---

```
(gen-servlets-refreshed file) → (-> response?)  
  file : path-string?
```

Returns a function that generates a standard "Servlet cache refreshed." message with content from *file*.

---

```
(gen-passwords-refreshed file) → (-> response?)  
  file : path-string?
```

Returns a function that generates a standard "Passwords refreshed." message with content from *file*.

---

```
(gen-authentication-responder file)
```

```
→ ((url url?) (header header?) . -> . response?)  
  file : path-string?
```

Returns a function that generates an authentication failure error with content from *file* and *header* as the HTTP header.

---

```
(gen-protocol-responder file) → ((url url?) . -> . response?)  
  file : path-string?
```

Returns a function that generates a "Malformed request" error with content from *file*.

---

```
(gen-file-not-found-responder file)  
→ ((req request?) . -> . response?)  
  file : path-string?
```

Returns a function that generates a standard "File not found" error with content from *file*.

---

```
(gen-collect-garbage-responder file) → (-> response?)  
  file : path-string?
```

Returns a function that generates a standard "Garbage collection run" message with content from *file*.

## 5 Internal APIs

The Web Server is a complicated piece of software and as a result, defines a number of interesting and independently useful sub-components. Some of these are documented here.

### 5.1 Timers

```
(require web-server/private/timer)
```

This module provides a functionality for running procedures after a given amount of time, that may be extended.

---

```
(struct timer (evt expire-seconds action)
  #:extra-constructor-name make-timer)
  evt : evt?
  expire-seconds : number?
  action : (-> void)
```

`evt` is an `alarm-evt` that is ready at `expire-seconds`. `action` should be called when this `evt` is ready.

---

```
(start-timer-manager) → void
```

Handles the execution and management of timers.

---

```
(start-timer s action) → timer?
  s : number?
  action : (-> void)
```

Registers a timer that runs `action` after `s` seconds.

---

```
(reset-timer! t s) → void
  t : timer?
  s : number?
```

Changes `t` so that it will fire after `s` seconds.

---

```
(increment-timer! t s) → void
  t : timer?
  s : number?
```

Changes *t* so that it will fire after *s* seconds from when it does now.

---

```
(cancel-timer! t) → void
  t : timer?
```

Cancels the firing of *t* ever and frees resources used by *t*.

## 5.2 Connection Manager

```
(require web-server/private/connection-manager)
```

This module provides functionality for managing pairs of input and output ports. We have plans to allow a number of different strategies for doing this.

---

```
(struct connection (timer i-port o-port custodian close?)
  #:extra-constructor-name make-connection)
  timer : timer?
  i-port : input-port?
  o-port : output-port?
  custodian : custodian?
  close? : boolean?
```

A connection is a pair of ports (*i-port* and *o-port*) that is ready to close after the current job if *close?* is *#t*. Resources associated with the connection should be allocated under *custodian*. The connection will last until *timer* triggers.

---

```
(start-connection-manager) → void
```

Runs the connection manager (now just the timer manager).

---

```
(new-connection timeout
  i-port
  o-port
  cust
  close?) → connection?
  timeout : number?
  i-port : input-port?
  o-port : output-port?
  cust : custodian?
  close? : boolean?
```

Constructs a connection with a timer with a trigger of `timeout` that calls `kill-connection!`.

---

```
(kill-connection! c) → void
  c : connection?
```

Closes the ports associated with `c`, kills the timer, and shuts down the custodian.

---

```
(adjust-connection-timeout! c t) → void
  c : connection?
  t : number?
```

Calls `increment-timer!` with the timer behind `c` with `t`.

### 5.3 Serializable Closures

The defunctionalization process of the Web Language (see §3 “Stateless Servlets”) requires an explicit representation of closures that is serializable.

```
(require web-server/lang/serial-lambda)
```

---

```
(serial-lambda formals body ...)
```

Returns `(lambda formals body ...)`, except it is serializable.

---

```
(serial-case-lambda [formals body ...] ...)
```

Returns `(case-lambda [formals body ...] ...)`, except it is serializable.

#### 5.3.1 Definition Syntax

```
(require web-server/private/define-closure)
```

---

```
(define-closure tag formals (free-var ...) body)
```

Defines a closure, constructed with `make-tag` that accepts a closure that returns `freevar ...`, that when invoked with `formals` executes `body`.

Here is an example:

```
#lang racket
```

```

(require racket/serialize)

(define-closure foo (a b) (x y)
  (+ (- a b)
     (* x y)))

(define f12 (make-foo (lambda () (values 1 2))))
(serialize f12)
'((1) 1 (('page . foo:deserialize-info)) 0 () () (0 1 2))
(f12 6 7)
1
(f12 9 1)
10

(define f45 (make-foo (lambda () (values 4 5))))
(serialize f45)
'((1) 1 (('page . foo:deserialize-info)) 0 () () (0 4 5))
(f45 1 2)
19
(f45 8 8)
20

```

## 5.4 Cache Table

```
(require web-server/private/cache-table)
```

This module provides a set of caching hash table functions.

---

```
(make-cache-table) → cache-table?
```

Constructs a cache-table.

---

```
(cache-table-lookup! ct id mk) → any/c
  ct : cache-table?
  id : symbol?
  mk : (-> any/c)
```

Looks up *id* in *ct*. If it is not present, then *mk* is called to construct the value and add it to *ct*.

---

```
(cache-table-clear! ct) → void?
  ct : cache-table?
```

Clears all entries in *ct*.

---

```
(cache-table? v) → boolean?  
  v : any/c
```

Determines if *v* is a cache table.

## 5.5 MIME Types

```
(require web-server/private/mime-types)
```

This module provides function for dealing with "mime.types" files.

---

```
(read-mime-types p) → (hash/c symbol? bytes?)  
  p : path-string?
```

Reads the "mime.types" file from *p* and constructs a hash table mapping extensions to MIME types.

---

```
(make-path->mime-type p) → (path? . -> . bytes?)  
  p : path-string?
```

Uses a `read-mime-types` with *p* and constructs a function from paths to their MIME type.

## 5.6 Serialization Utilities

```
(require web-server/private/mod-map)
```

The `racket/serialize` library provides the functionality of serializing values. This module compresses the serialized representation.

---

```
(compress-serial sv) → list?  
  sv : list?
```

Collapses multiple occurrences of the same module in the module map of the serialized representation, *sv*.

---

```
(decompress-serial csv) → list?  
  csv : list?
```

Expands multiple occurrences of the same module in the module map of the compressed serialized representation, *csv*.

## 5.7 URL Param

```
(require web-server/private/url-param)
```

The Web Server needs to encode information in URLs. If this data is stored in the query string, than it will be overridden by browsers that make GET requests to those URLs with more query data. So, it must be encoded in URL params. This module provides functions for helping with this process.

---

```
(insert-param u k v) → url?  
  u : url?  
  k : string?  
  v : string?
```

Associates *k* with *v* in the final URL param of *u*, overwriting any current binding for *k*.

---

```
(extract-param u k) → (or/c string? false/c)  
  u : url?  
  k : string?
```

Extracts the string associated with *k* in the final URL param of *u*, if there is one, returning *#f* otherwise.

## 5.8 GZip

```
(require web-server/private/gzip)
```

The Web Server provides a thin wrapper around *file/gzip* and *file/gunzip*.

---

```
(gzip/bytes ib) → bytes?  
  ib : bytes?
```

GZips *ib* and returns the result.

---

```
(gunzip/bytes ib) → bytes?  
  ib : bytes?
```

GUnzips *ib* and returns the result.

## 6 Troubleshooting and Tips

### 6.1 How do I use Apache with the Racket Web Server?

You may want to put Apache in front of your Racket Web Server application. Apache can rewrite and proxy requests for a private (or public) Racket Web Server:

```
RewriteEngine on
RewriteRule ^(.*)$ http://localhost:8080/$1 [P,NE]
```

The first argument to `RewriteRule` is a match pattern. The second is how to rewrite the URL. The bracketed part contains flags that specify the type of rewrite, in this case the `P` flag instructs Apache to proxy the request. (If you do not include this, Apache will return an HTTP Redirect response and the client will make a second request to `localhost:8080` which will not work on a different machine.) In addition, the `NE` flag is needed to avoid escaping parts of the URL — without it, a `;` is escaped as `%3B` which will break the proxied request.

See Apache's documentation for more details on `RewriteRule`.

### 6.2 Can the server create a PID file?

The server has no option for this, but you can add it very easily. There's two techniques.

First, if you use a UNIX platform, in your shell startup script you can use

```
echo $$ > PID
exec run-web-server
```

Using `exec` will reuse the same process, and therefore, the PID file will be accurate.

Second, if you want to make your own Racket start-up script, you can write:

```
(require mzlib/os)
(with-output-to-file your-pid-file (lambda () (write (getpid))))
(start-server)
```

### 6.3 How do I set up the server to use HTTPS?

This requires an SSL certificate and private key. This is very platform specific, but we will provide the details for using OpenSSL on UNIX:

```
openssl genrsa -des3 -out private-key.pem 1024
```

This will generate a new private key, but it will have a passphrase on it. You can remove this via:

```
openssl rsa -in private-key.pem -out private-key.pem  
chmod 400 private-key.pem
```

Now, we generate a self-signed certificate:

```
openssl req -new -x509 -nodes -sha1 -days 365 -key private-key.pem  
> server-cert.pem
```

(Each certificate authority has different instructions for generating certificate signing requests.)

We can now start the server with:

```
plt-web-server --ssl
```

The Web Server will start on port 443 (which can be overridden with the `-p` option) using the "private-key.pem" and "server-cert.pem" we've created.

## **6.4 How do I limit the number of requests serviced at once by the Web Server?**

Refer to §2.14 "Limiting Requests".
